## Instruments

All ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ nuclear magnetic resonance spectra were obtained using a 300 MHz Varian VNMRS, 400 MHz Varian Unity Inova or 600 MHz Varian Unity Inova NMR instrument using deuterated solvents. Chemical shifts ( $\delta$ ) were recorded using the residual solvent peak or external reference (TMS). All chemical shifts are reported in parts per million and all spectra were obtained at $25{ }^{\circ} \mathrm{C}$. Data was processed using ACD/SpecManager product version 12.01.

Melting points were obtained using a Stuart Scientific Melting Point Apparatus in open capillaries. Infrared spectra were obtained using a Nicolet Avatar 330 FT-IR instrument as neat samples (ATR). High resolution mass spectrometry was performed by CAF (Central Analytical Facility) at Stellenbosch University using a Waters Synapt G2 spectrometer. Metal analysis by ICP-AES was performed by CAF (Central Analytical Facility) at Stellenbosch University using a Thermo Scientific iCAP 6000 Series instrument. Ion chromatography data was obtained on a DIONEX DX-120 instrument. Single crystal data was collected on a Bruker SMART Apex CCD diffractometer using graphite monochromated $\mathrm{Mo}-\mathrm{K}_{\alpha}$ radiation $(\lambda=0.71073 \AA)$. The temperature of the crystals was controlled using an Oxford Cryostream Cooler. Data reduction was carried out by means of a standard procedure using the Bruker software package SAINT. ${ }^{1}$ Where necessary, systematic errors in the intensity data were corrected by using SADABS. ${ }^{2,3}$ File preparation was done with XPrep and structures were solved by direct methods or a combination of Patterson and partial structure expansion using SHELXS-97. ${ }^{4}$ In most cases, all non-hydrogen atoms were located using either of these methods. All ordered non-hydrogen atoms were refined anisotropically by means of full-matrix least squares calculations of $F^{2}$ using SHELXL- $97{ }^{4}$ within the X-Seed ${ }^{5}$ environment. Where appropriate, the hydrogen atoms were placed in calculated positions using riding models and assigned isotropic thermal parameters 1.2 times those of their parent atoms.

### 1.2 Procedures and characterisation data

## Ligand 1 (L1)

## 2. Solvent Extraction - Metal Salt Extraction and Transport

### 2.1 Solvent extraction of metal ions

A 0.01 M solution of each ligand in chloroform $\left(5 \mathrm{~cm}^{3}\right)$ was contacted with a buffer solution at pH 5.09 containing a 0.01 M mixture of the $\mathrm{Cu}(\mathrm{II}), \mathrm{Zn}(\mathrm{II}), \mathrm{Ni}(\mathrm{II}), \mathrm{Co}$ (II), $\mathrm{Pb}(\mathrm{II})$ and $\mathrm{Cd}(\mathrm{II})$ metal ions $\left(5 \mathrm{~cm}^{3}\right)$ and shaken on a labcon-oscillating shaker at 120 rpm for 24 h . Extraction was performed at $25^{\circ} \mathrm{C}$. The aqueous phase was removed and a sample was taken and used for metal ion analysis by ICP-AES. The results are quoted as the average value obtained from duplicate runs. Any apparent extraction of a metal ion of less than $2.0 \%$ was assumed to be within the experimental error of zero and hence ignored in the treatment of results. In all cases the values between any two duplicate runs
did not differ by more than $2 \%$. Figure S1 shows the colour changes in the different phases before and after metal ion extraction. The results of the extraction are indicated in Figure S2.

Figure S1: (i) Before and (ii) after images of solvent extraction using different metal ions for each of the ligands (performed in duplicate).

Figure S2: Percentage extraction of $\mathrm{Cd}(\mathrm{II}), \mathrm{Co}(\mathrm{II}), \mathrm{Cu}(\mathrm{II}), \mathrm{Ni}(\mathrm{II}), \mathrm{Pb}(\mathrm{II})$ and $\mathrm{Zn}(\mathrm{II})$ by each of the ligands.

### 2.2 Solvent extraction of $\mathbf{C u}(I I)$ at different $\mathbf{p H}$ values

A 0.01 M solution of $\mathbf{L} \mathbf{2}$ in chloroform $\left(5 \mathrm{~cm}^{3}\right)$ was contacted with a $5 \mathrm{~cm}^{3}$ solution of 0.01 M $\mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ at $\mathrm{pH} 1.30,2.07,2.13,3.38,3.80,4.43,4.92$ and 5.83 respectively and shaken on a labcon-oscillating shaker at 120 rpm for 24 h . Extraction was performed at $25^{\circ} \mathrm{C}$. The aqueous phase was removed and a sample was taken and used for metal analysis by ICP-AES.

Figure S3: (i) Before and (ii) after images of solvent extraction of $\mathrm{Cu}(\mathrm{II})$ at different pH values for $\mathbf{L} 2$.

Figure S3 shows the colour changes in the different phases before and after metal ion extraction. By measuring the copper(II) ion content of the aqueous phase and plotting the percentage loading values against the equilibrium pH of the aqueous phase, it is possible to determine the metal ion loading S curve, indicated in Figure S4.

### 2.3 Solvent extraction of $\mathrm{SO}_{4}^{2-}, \mathrm{NO}_{3}^{-}$or Cl by the copper-only complexes

A 0.01 M solution of $\mathbf{L} \mathbf{2}$ and $\mathbf{L} \mathbf{3}$ respectively in chloroform $\left(5 \mathrm{~cm}^{3}\right)$ was contacted with a solution containing a mixture of $0.01 \mathrm{M} \mathrm{CuSO}_{4} \cdot 5 \mathrm{H}_{2} \mathrm{O}, 0.005 \mathrm{M} \mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2} \cdot 3 \mathrm{H}_{2} \mathrm{O}$, and $0.005 \mathrm{M} \mathrm{CuCl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ at $\mathrm{pH} 2.51\left(5 \mathrm{~cm}^{3}\right)$ and shaken on a labcon-oscillating shaker at 120 rpm for 24 h . Extraction was performed at $25^{\circ} \mathrm{C}$. The aqueous phase was removed and a sample was taken and used for ion analysis by ion chromatography. The results are quoted as the average value obtained from duplicate runs. Any apparent extraction of an anion of less than $2.0 \%$ was assumed to be within the experimental error of zero and hence ignored in the treatment of results. In all cases the values
between any two duplicate runs did not differ by more than $2 \%$. Figure S 7 shows the phases before solvent extraction. Note that for $\mathbf{L} \mathbf{2}$ extraction has started as soon as the two phases were added together. The results of the experiment are indicated in Table S1.

### 2.4 Membrane transport of metal ions:

Each ligand, at a concentration of 0.002 M was used separately as a carrier for the transport of metal ions across a $\mathrm{CHCl}_{3}\left(50 \mathrm{~cm}^{3}\right)$ bulk liquid membrane. Details of the cell design have been reported elsewhere ${ }^{6}$. The source phase consisted of $10 \mathrm{~cm}^{3}$ of a 0.01 M solution of $\mathrm{Cu}(\mathrm{II}), \mathrm{Zn}$ (II), Co (II), $\mathrm{Ni}($ II $), \mathrm{Pb}$ (II) and Cd (II) metal ions in a $\mathrm{CH}_{3} \mathrm{COONa}^{2} / \mathrm{CH}_{3} \mathrm{COOH}$ buffer at pH 5.09 . The receiving phase consisted of $30 \mathrm{~cm}^{3}$ of $0.1 \mathrm{M} \mathrm{HNO}_{3}$ at pH 1.0 . All three phases in the transport cell were stirred at 10 rpm at $25^{\circ} \mathrm{C}$. Under these conditions, not only was the stirring process consistent, but also the interface between the organic membrane and the two aqueous phases remained flat and well defined. The cells were covered with slips to prevent any evaporation of solvents over the 24 h period.

Samples of the source and receiving phases were taken and used for metal analysis by ICP-AES. Figure S6 indicates the phases before and after the transport studies. The results are quoted in Table S4 as the average value obtained from duplicate runs. Any apparent extraction of a metal ion of less than 2.0 \% was assumed to be within the experimental error of zero and hence ignored in the treatment of results. In all cases the values between any two duplicate runs did not differ by more than $5 \%$.

### 2.5 Membrane transport of anions

$\mathbf{L} \mathbf{2}$ and $\mathbf{L} 3$, each at a concentration of 0.002 M were used as carriers for the transport of anions across a $\mathrm{CHCl}_{3}\left(50 \mathrm{~cm}^{3}\right)$ bulk liquid membrane. Details of the cell design have been reported elsewhere ${ }^{6}$. The source phase contained $10 \mathrm{~cm}^{3}$ of a 0.01 M solution of $0.01 \mathrm{M} \mathrm{CuSO}_{4}, \mathrm{HNO}_{3}$ and HCl at pH 1.91 . The receiving phase contained $30 \mathrm{~cm}^{3} \mathrm{NaH}_{2} \mathrm{PO}_{4} / \mathrm{Na}_{2} \mathrm{HPO}_{4}$ buffer at pH 6.95 . All three phases in the transport cell were stirred at 10 rpm at $25^{\circ} \mathrm{C}$. Under these conditions, not only was the stirring process consistent, but also the interface between the organic membrane and the two aqueous phases remained flat and well defined. The cells were covered with slips to prevent any evaporation of solvents over the 24 h period. Samples of the source phase and the receiving phase were taken and used for ion chromatography. Figure S7 indicates the phases before and after the transport studies. The results are quoted as the average value obtained from duplicate runs in Table S3. Any apparent extraction of a metal ion of less than $2.0 \%$ was assumed to be within the experimental error of zero and hence ignored in the treatment of results. In all cases the values between any two duplicate runs did not differ by more than $5 \%$.
